

Possible identification of dinosaur which made the primary prints at the Taylor site.

DIMORPHODON⁵²

The creature which made the original tracks at the Taylor site remains unknown. It is possible that more than one dinosaur was present while the substrate was still pliable.

Careful analysis of available site data does offer some interesting possibilities for general identification. Coloration in the IOxW trail indicated a web footed candidate. Two claws show prominently in color beside one footprint. These data plus depth and general elongated foot contour suggest the possibility that a pterosaur such as Dimorphodon could have been on the scene.
